Building an International Flagship Neutrino Experiment

An international team of over 1,400 scientists and engineers from more than 35 countries is building the most advanced neutrino experiment in the world. Hosted by the U.S. Department of Energy’s Fermilab with contributions from across the U.S. and around the globe, the Deep Underground Neutrino Experiment could change our understanding of the universe. Excavation of the caverns in South Dakota is more than 70% complete, and the UK, CERN and other partners are producing and testing detector components.

Deep Underground Neutrino Experiment (DUNE)
DUNE consists of two state-of-the-art particle detectors: a smaller one at Fermilab in Illinois and a much larger one to be constructed a mile beneath the surface at the Sanford Underground Research Facility in South Dakota. The South Dakota detector will be the largest of its type ever built. It will use 70,000 tons of liquid argon and advanced technology to record neutrino interactions with unprecedented precision. Collaborators in the UK have begun the mass production of components for the first of four huge particle detector modules for DUNE. Testing is taking place at CERN. DUNE collaborators also are working on components for the detector at Fermilab.

Long-Baseline Neutrino Facility (LBNF)
LBNF will house the DUNE far detector in South Dakota, as well as the smaller near detector at Fermilab. About 800,000 tons of rock is being moved from a mile underground at the Sanford Underground Research Facility. The excavation is more than 70% complete. The new space will be equipped with intricate cryogenic technology to keep the DUNE detector at its operating temperature of ~300 degrees Fahrenheit. At Fermilab, a new beamline will be built to send the laboratory’s intense high-energy beam of neutrinos 800 miles through the earth from Illinois to South Dakota. The neutrinos will travel straight through earth, no tunnel needed.

Proton Improvement Plan II (PIP-II)
The DUNE experiment requires the most particle-packed high-energy neutrino beam in the world, and that’s exactly what Fermilab will deliver. A new, 700-foot-long particle accelerator, built with major contributions from partners around the world, will power the intense neutrino beam. The accelerator will be built with the latest superconducting radio-frequency technology developed at Fermilab. Tests at the PIP-II Injector Test Facility successfully concluded in 2021, including the acceleration of protons through a superconducting section. The PIP-II cryoplant building was completed in 2022. Construction of the complex that will house the accelerator has begun.
Why neutrinos?
The Deep Underground Neutrino Experiment, powered by the Long-Baseline Neutrino Facility and Fermilab’s PIP-II accelerator upgrades, will study elusive subatomic particles called neutrinos. They are the most abundant matter particles in the universe, and they are all around us, but we know very little about them. Each second a trillion neutrinos pass harmlessly through our bodies. In nature, they are produced in great quantities by the sun and other stars.

Scientists can create neutrinos in the laboratory with huge particle accelerators, and these neutrinos can be tracked with extremely sensitive detectors. Learning more about neutrinos, particularly the unique mechanism that allows them to change from one type to another over long distances, will tell us more about the universe and how it works. It may even give us the key to understanding why we live in a matter-dominated universe—in other words, why we are here.

Three major discovery areas

DUNE scientists will look at the differences in behavior between neutrinos and antineutrinos, aiming to find out whether neutrinos are the reason the universe is made of matter.

DUNE’s search for the signal of proton decay—a signal so rare it has never been seen—will move scientists closer to realizing Einstein’s dream of a unified theory of matter and energy.

DUNE will look for the gigantic streams of neutrinos emitted by exploding stars to watch the formation of neutron stars and black holes in real time, and learn more about these mysterious objects in space.

An international effort

The Deep Underground Neutrino Experiment brings together over 1,400 scientists and engineers from more than 35 countries around the world.

Project timeline

- Groundbreaking for LBNF/DUNE: July 2017
- First ProtoDUNE detector online at CERN: Sept. 2018
- Pre-excavation work begins in South Dakota: Jan. 2019
- LBNF/DUNE site preparation starts at Fermilab: Nov. 2019
- Begin main cavern excavation in South Dakota: 2021
- Begin installing the first DUNE detector: 2024
- Begin operating the first DUNE detector: 2028
